

A world map with a color gradient from light blue to yellow. Overlaid on the map are blue contour lines with numerical labels (2, 4, 6, 8) indicating values. The map shows a global pattern of these contours, with higher values (6 and 8) in the northern and southern high latitudes and lower values (2 and 4) in the mid and low latitudes.

# Why and How We Created JGOFS and The Lessons Learned

JGOFS Final Open Science Conference

Jim McCarthy

5 - 8 May 2003

# Some Important Dates

October 1982 - Ocean Science Board meeting

March 1983 - Small Cambridge meeting

June 1983 - Letter from Board on Ocean Science  
and Policy to James Beggs, Administrator of NASA

May 1984 - Boston Planning Meeting

September 1984 - The Woods Hole workshop

December 1984 - The workshop report was complete

Board on Ocean Science and Policy  
**ACTION ITEM**

“As a result of *discussions* at the last OSB meeting, a small group consisting of Baker, Broecker, McCarthy, Steel and Wunsch met on March 22, 1983 to consider the relations between plans for larger term research on physical, chemical, and biological oceanography.

The following statement is the outcome of this meeting:”

*AKA “The Truce”*

Spring 1983

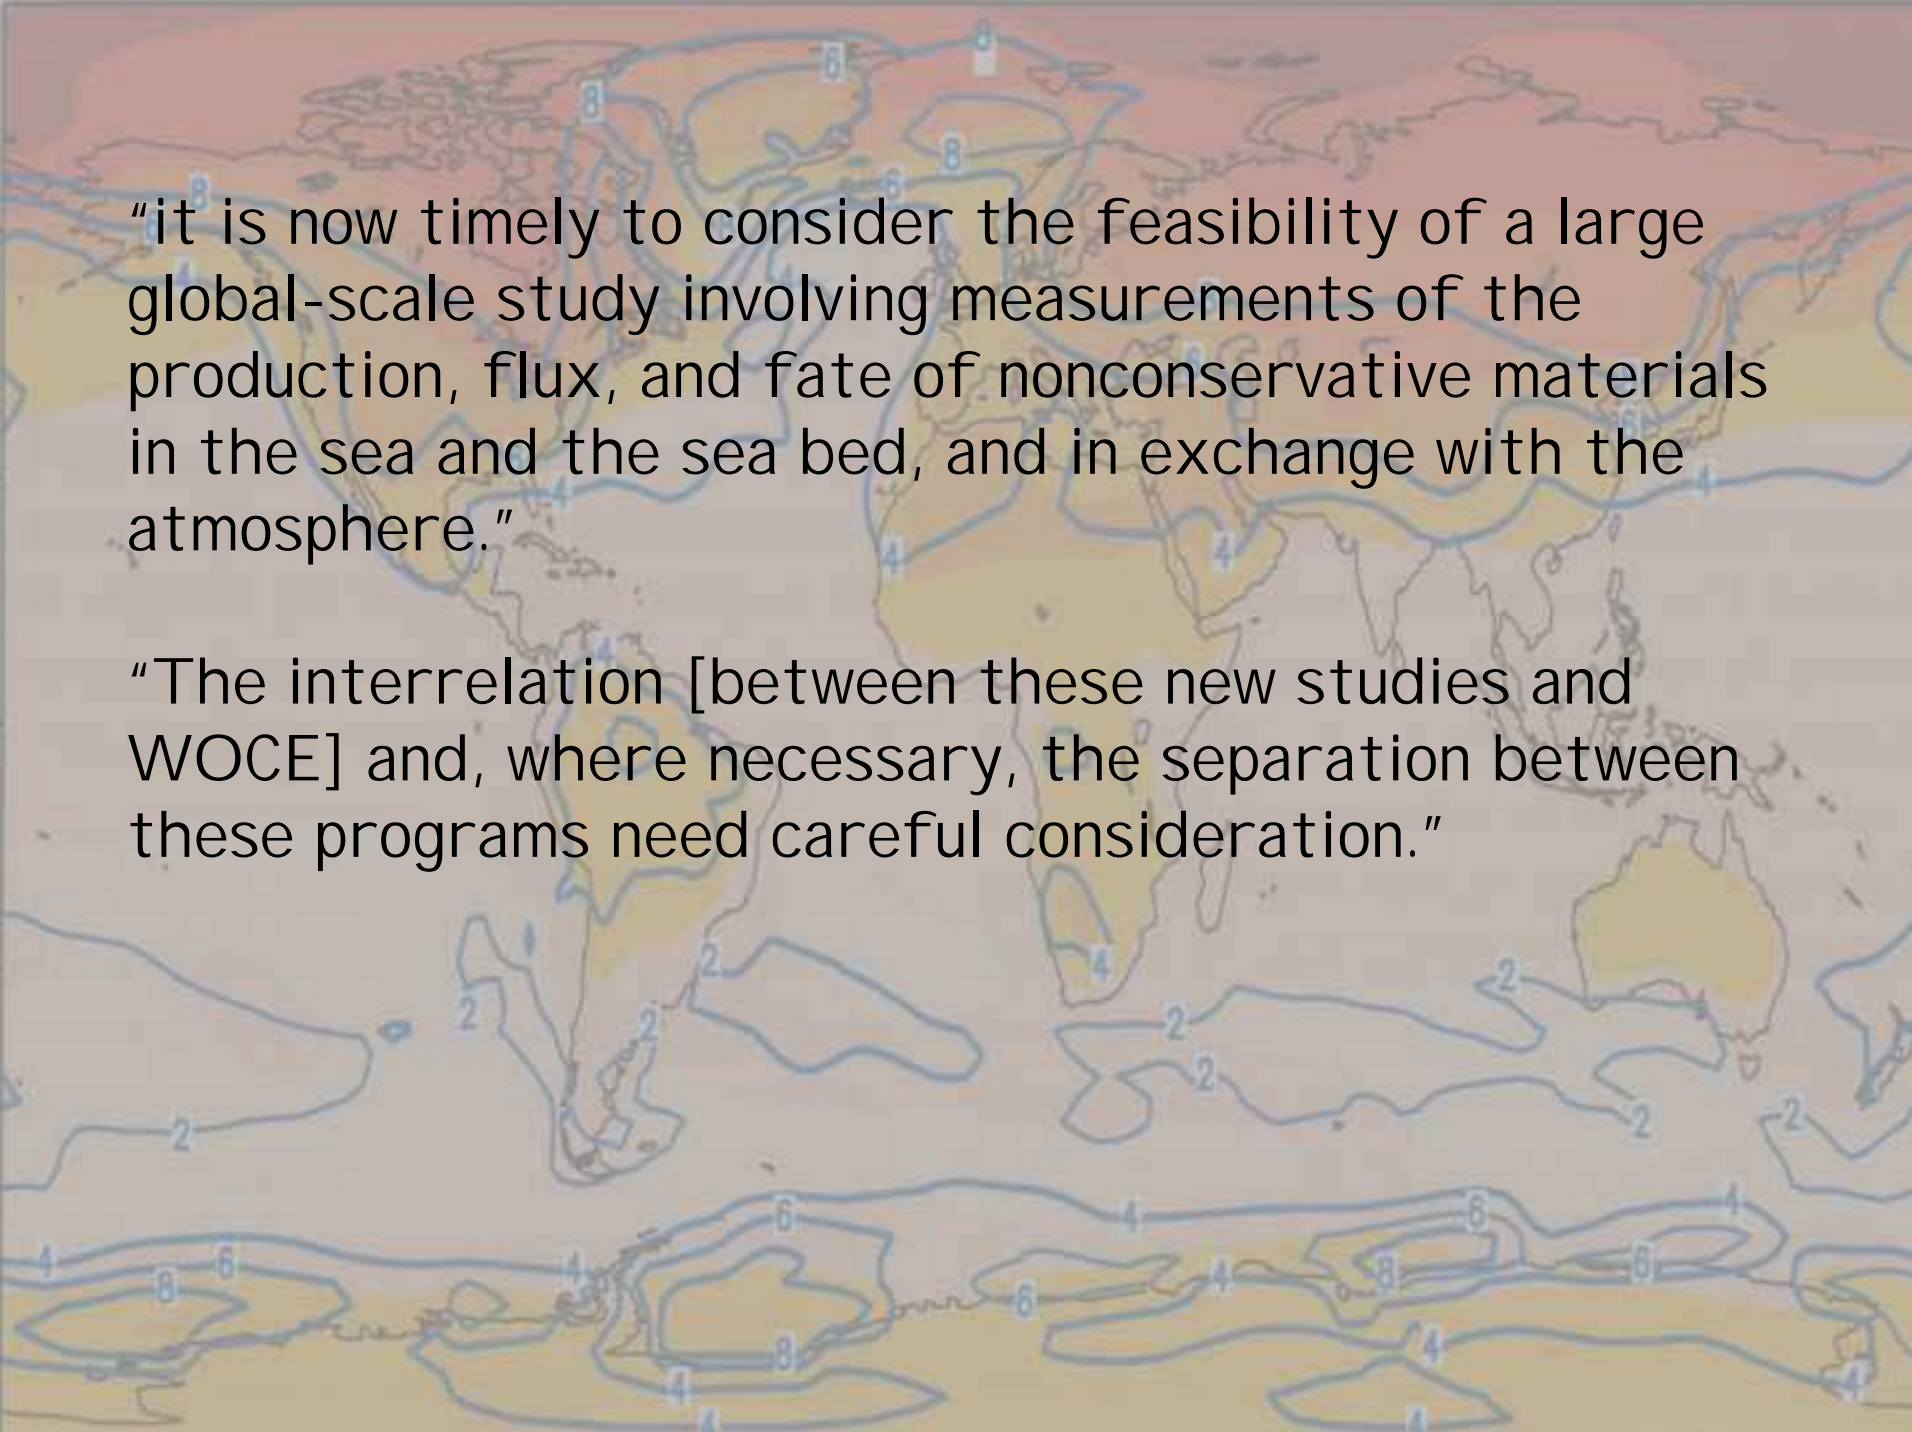

Excerpts:

“the planning and implementation of WOCE have a high priority”

“At the same time, however, there should be consideration of complementary programs concerned with the distribution and fluxes of nonconservative constituents ...especially those involved in critical organic pathways”

“The extrapolation to large scales can be accomplished by major expeditions such as GEOSECS & TTO, and by the use of remote sensing instruments such as the OCI ”

“it is now timely to consider the feasibility of a large global-scale study involving measurements of the production, flux, and fate of nonconservative materials in the sea and the sea bed, and in exchange with the atmosphere.”

“The interrelation [between these new studies and WOCE] and, where necessary, the separation between these programs need careful consideration.”

## Action

"The Board should consider appointing an ad hoc group consisting of J. Baker, W. Broecker, J. McCarthy, J. Steele, and C. Wunsch to outline the scope of a scientific flux program and to request NAS program initiation funds to hold meetings to discuss the feasibility of the study and to ascertain the interest of the federal agencies."

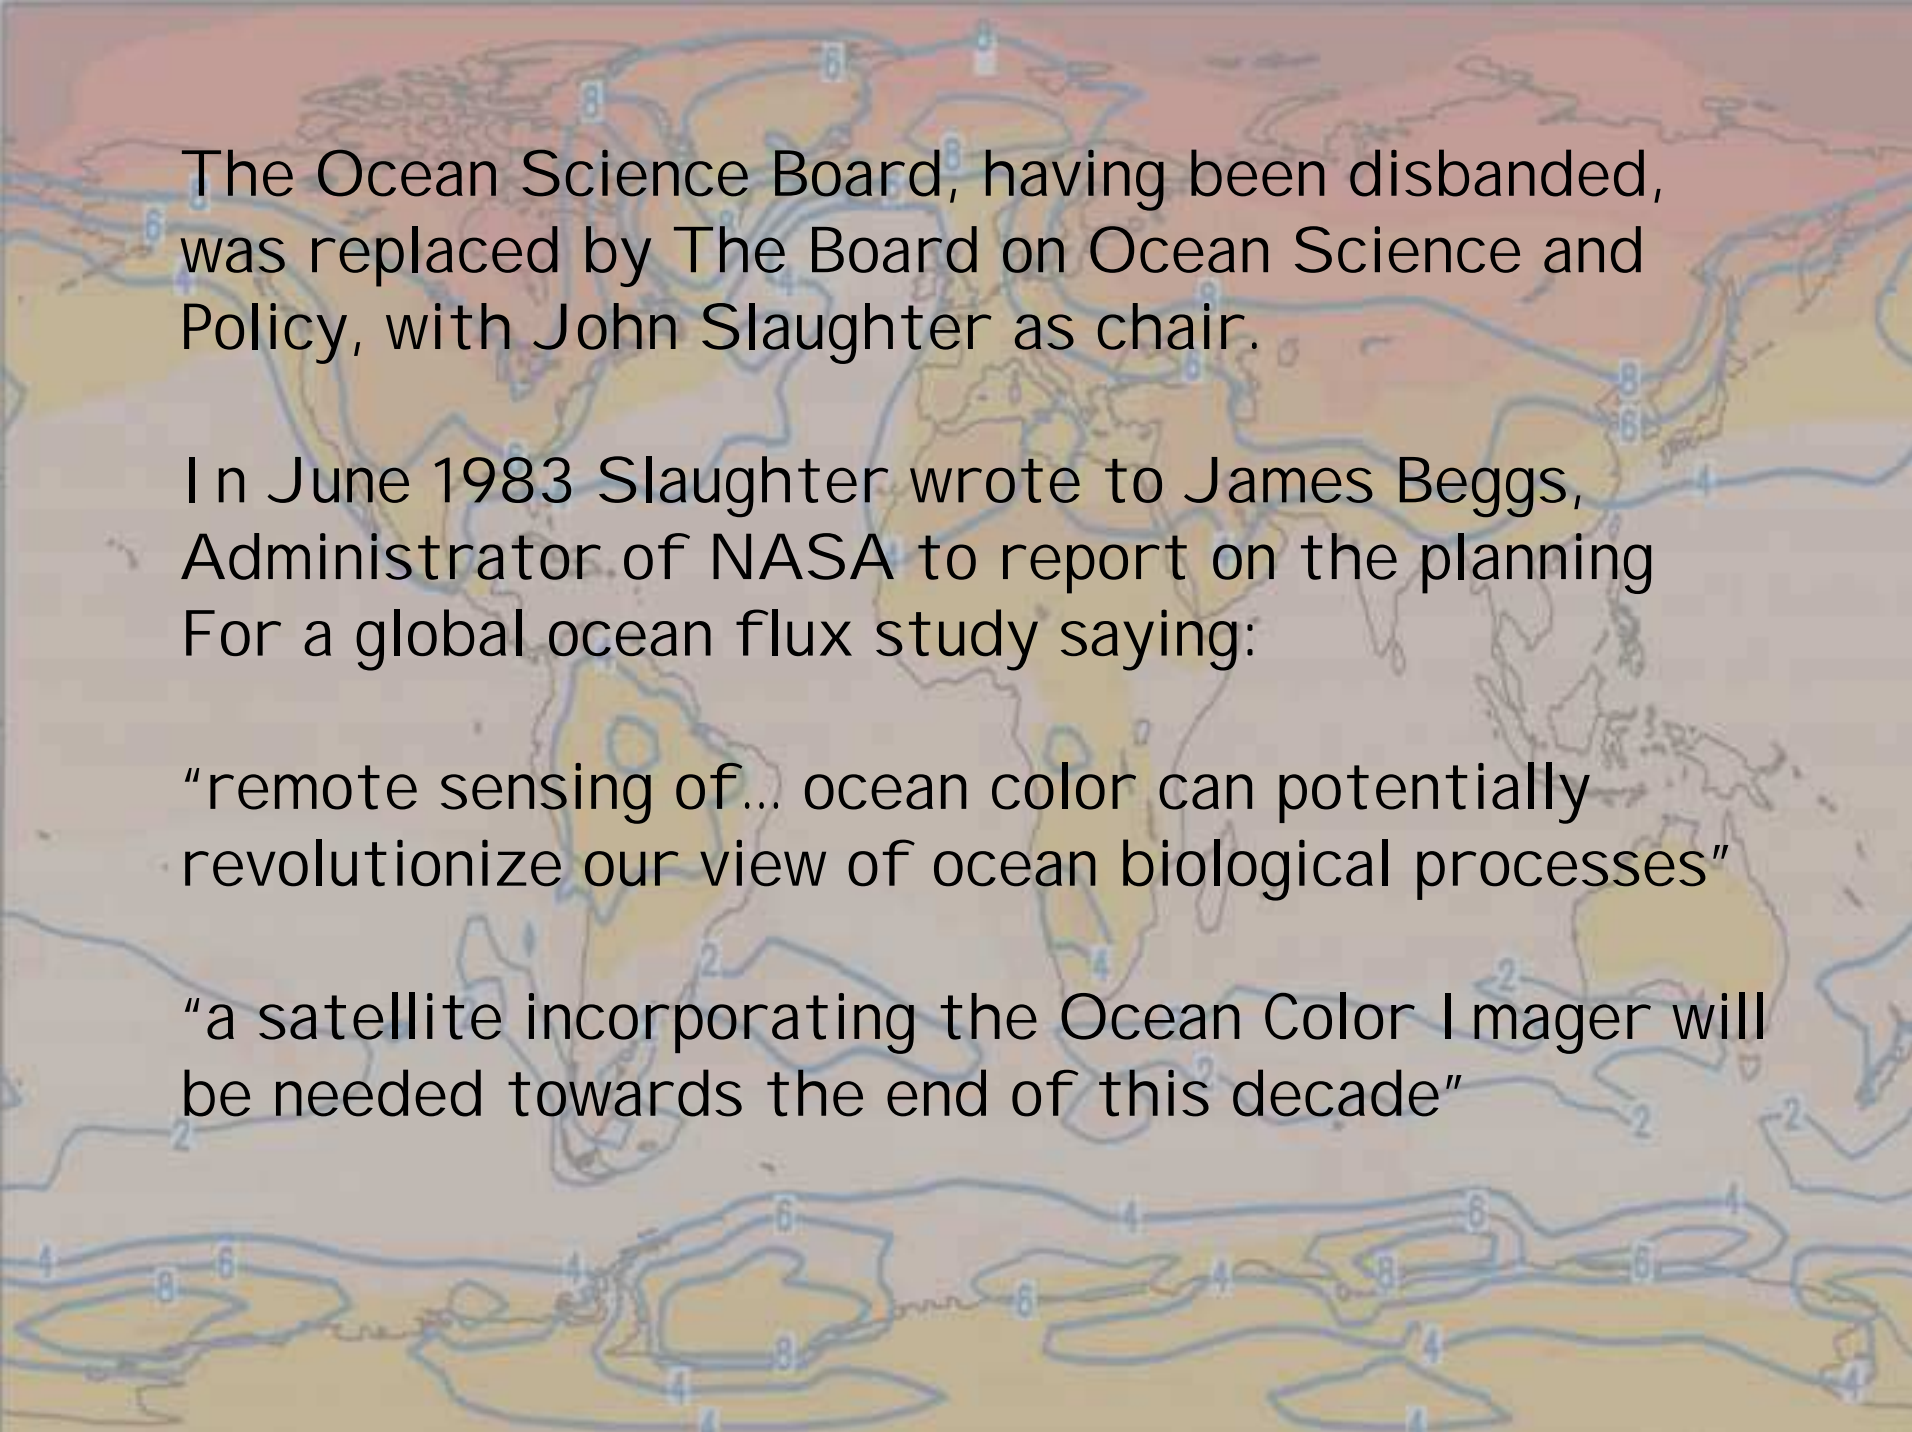

# Lesson Learned

Sort out disciplinary turf wars before  
wasting a lot of time on planning

# "Coastal Zone Color Scanner" (CZCS) May 1979

The background of the slide is a world map with overlaid contour lines representing oceanographic data, likely sea surface temperature or chlorophyll concentration. The contours are labeled with numbers such as 2, 4, 6, and 8, indicating different levels of the variable being measured. The map uses a color gradient from light yellow to light blue to represent the data values.

The Ocean Science Board, having been disbanded, was replaced by The Board on Ocean Science and Policy, with John Slaughter as chair.

In June 1983 Slaughter wrote to James Beggs, Administrator of NASA to report on the planning For a global ocean flux study saying:

“remote sensing of... ocean color can potentially revolutionize our view of ocean biological processes”

“a satellite incorporating the Ocean Color Imager will be needed towards the end of this decade”

"... the Board has... established an ad hoc committee chaired by John Steele to prepare a feasibility study of global biogeochemical cycles in the ocean."

"... your assurance of continued development of the OCI is needed."

*"Our views on the altimeter and scatterometer have been the subject of previous correspondence."*

"... the Board has... established an ad hoc committee chaired by John Steele to prepare a feasibility study of **global biogeochemical cycles** in the ocean."

"... your assurance of continued development of the OCI is needed."

*"Our views on the altimeter and scatterometer have been the subject of previous correspondence."*

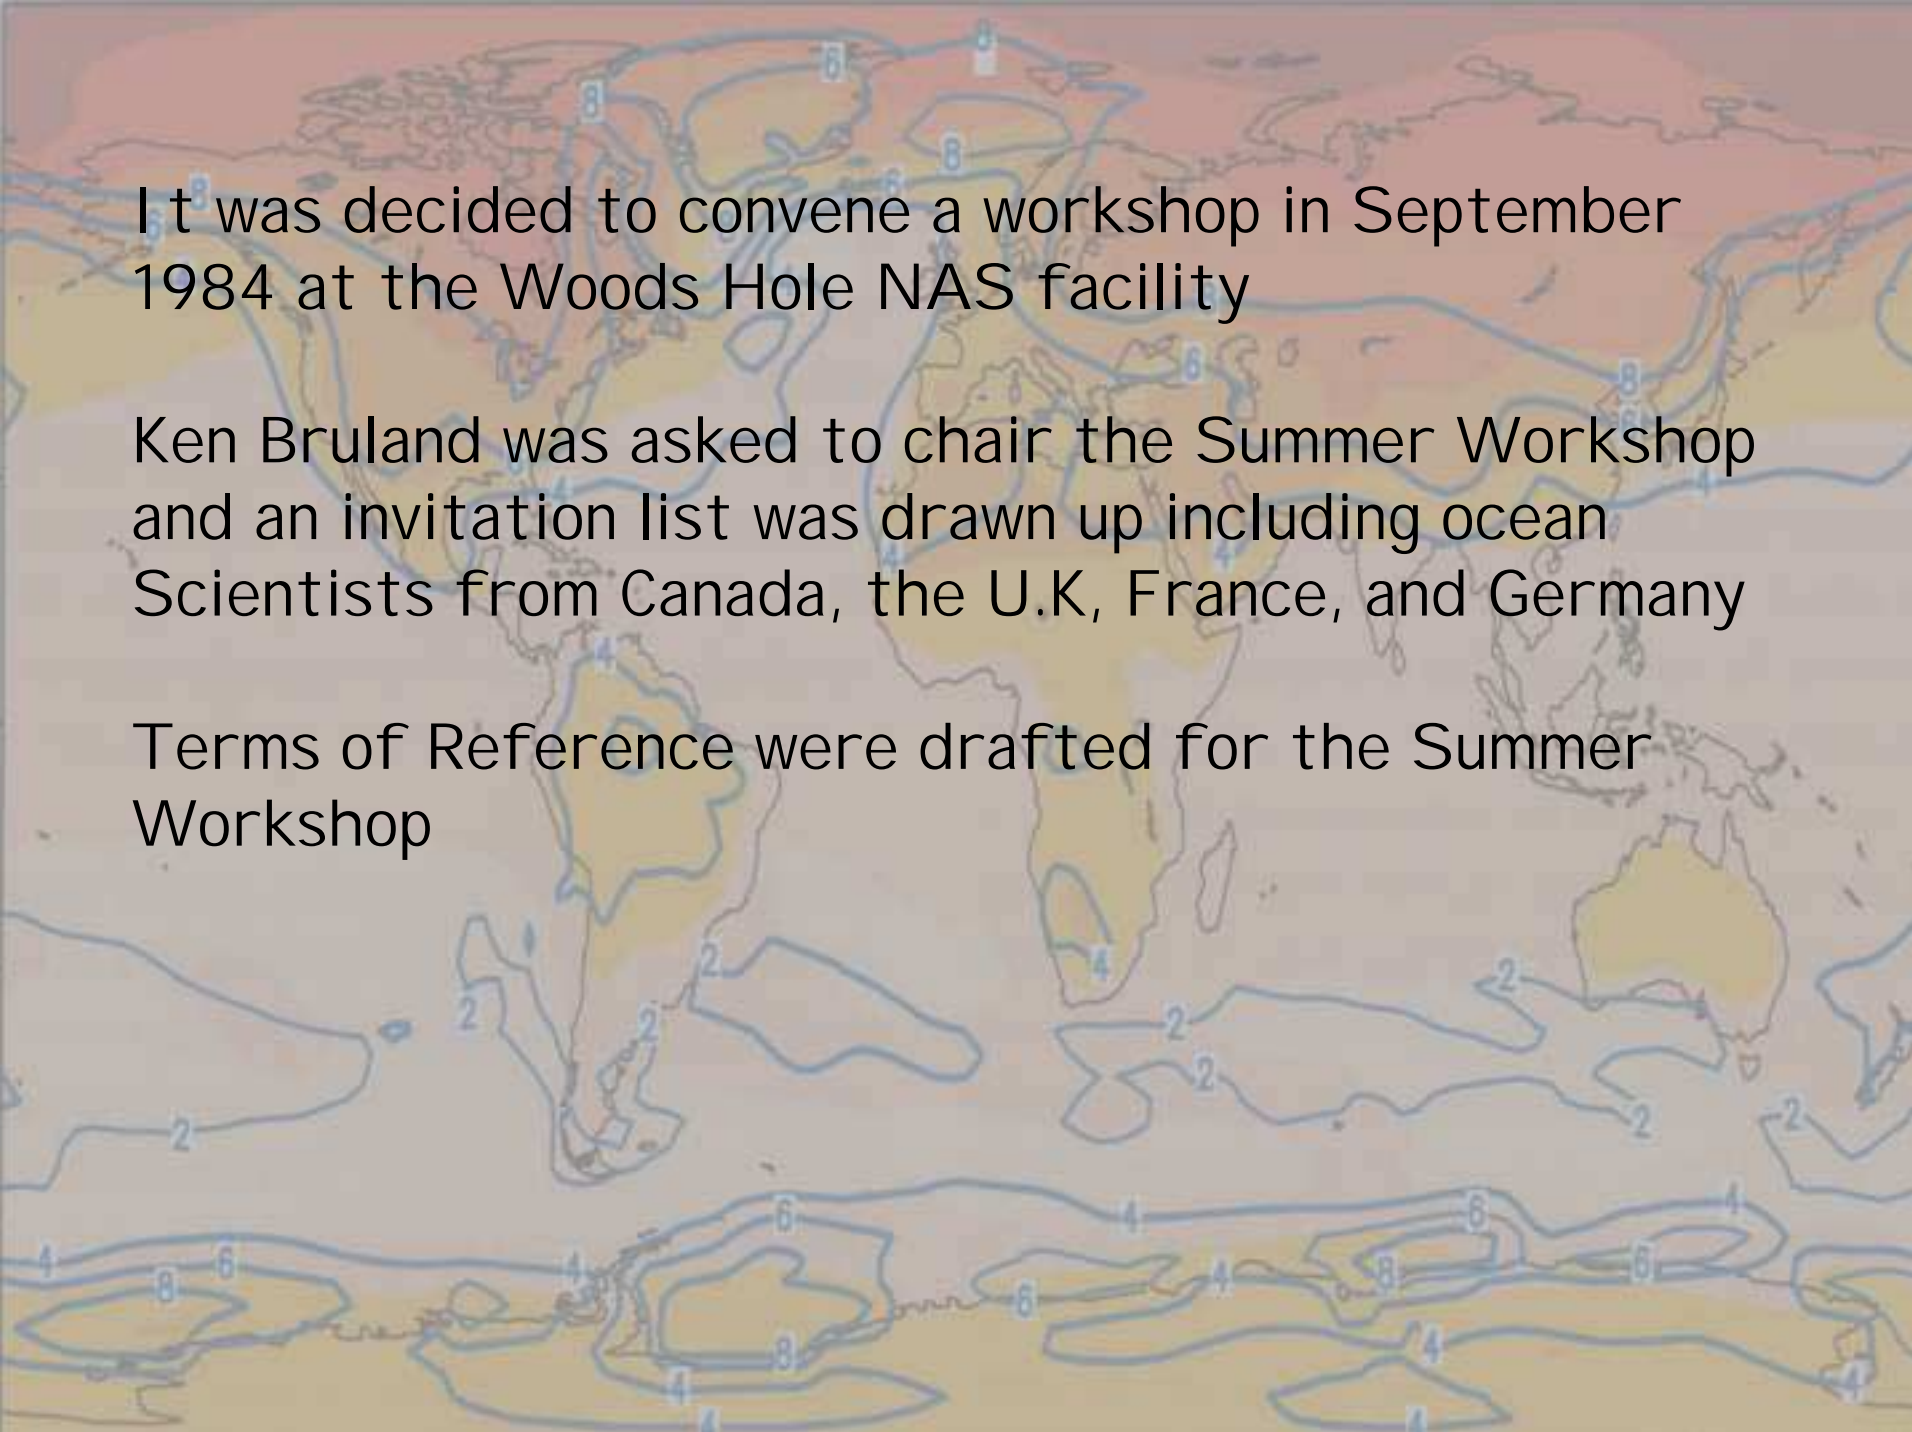

The background of the slide is a map of the Pacific Ocean. It features contour lines in shades of blue and yellow, with numerical values such as 2, 4, 6, and 8. The map shows the outlines of the continents of North America, South America, Africa, and Asia. The text is overlaid on this map.

# Planning Meeting for the Global Ocean Flux Study

Boston 8 May 1984

## Participants:

N. Anderson (NSF), D.J. Baker (JOI), W. Broecker,  
K. Bruland, R. Eppley, W. Esaias, G. Flierl, F. Herr (ONR),  
S. Honjo, W. Jenkins, J. McCarthy, J. Steele

A world map with a light beige background, overlaid with blue contour lines representing oceanographic data. The contours are labeled with numbers such as 2, 4, 6, and 8, indicating different levels of a specific variable. The map shows the outlines of continents and the distribution of these contours across the globe.

It was decided to convene a workshop in September 1984 at the Woods Hole NAS facility

Ken Bruland was asked to chair the Summer Workshop and an invitation list was drawn up including ocean Scientists from Canada, the U.K, France, and Germany

Terms of Reference were drafted for the Summer Workshop

## Terms of Reference for the Summer Workshop

- 1) To determine whether we have the potential to obtain ocean data on a global scale that could profoundly change our understanding of the flux of critical chemical constituents.
- 2) To identify the immediate and long-term objectives needed to achieve the Global Ocean Flux Program
- 3) If the ability is achievable, to determine the U.S. role in such an international program.
- 4) To outline the immediate steps necessary to assure that an appropriate program can be conducted within the next decade.

# Global Ocean Flux Study

*Proceedings of a Workshop*

1984

About 60 scientists (from 7 nations) participated and a broad overall goal was formulated

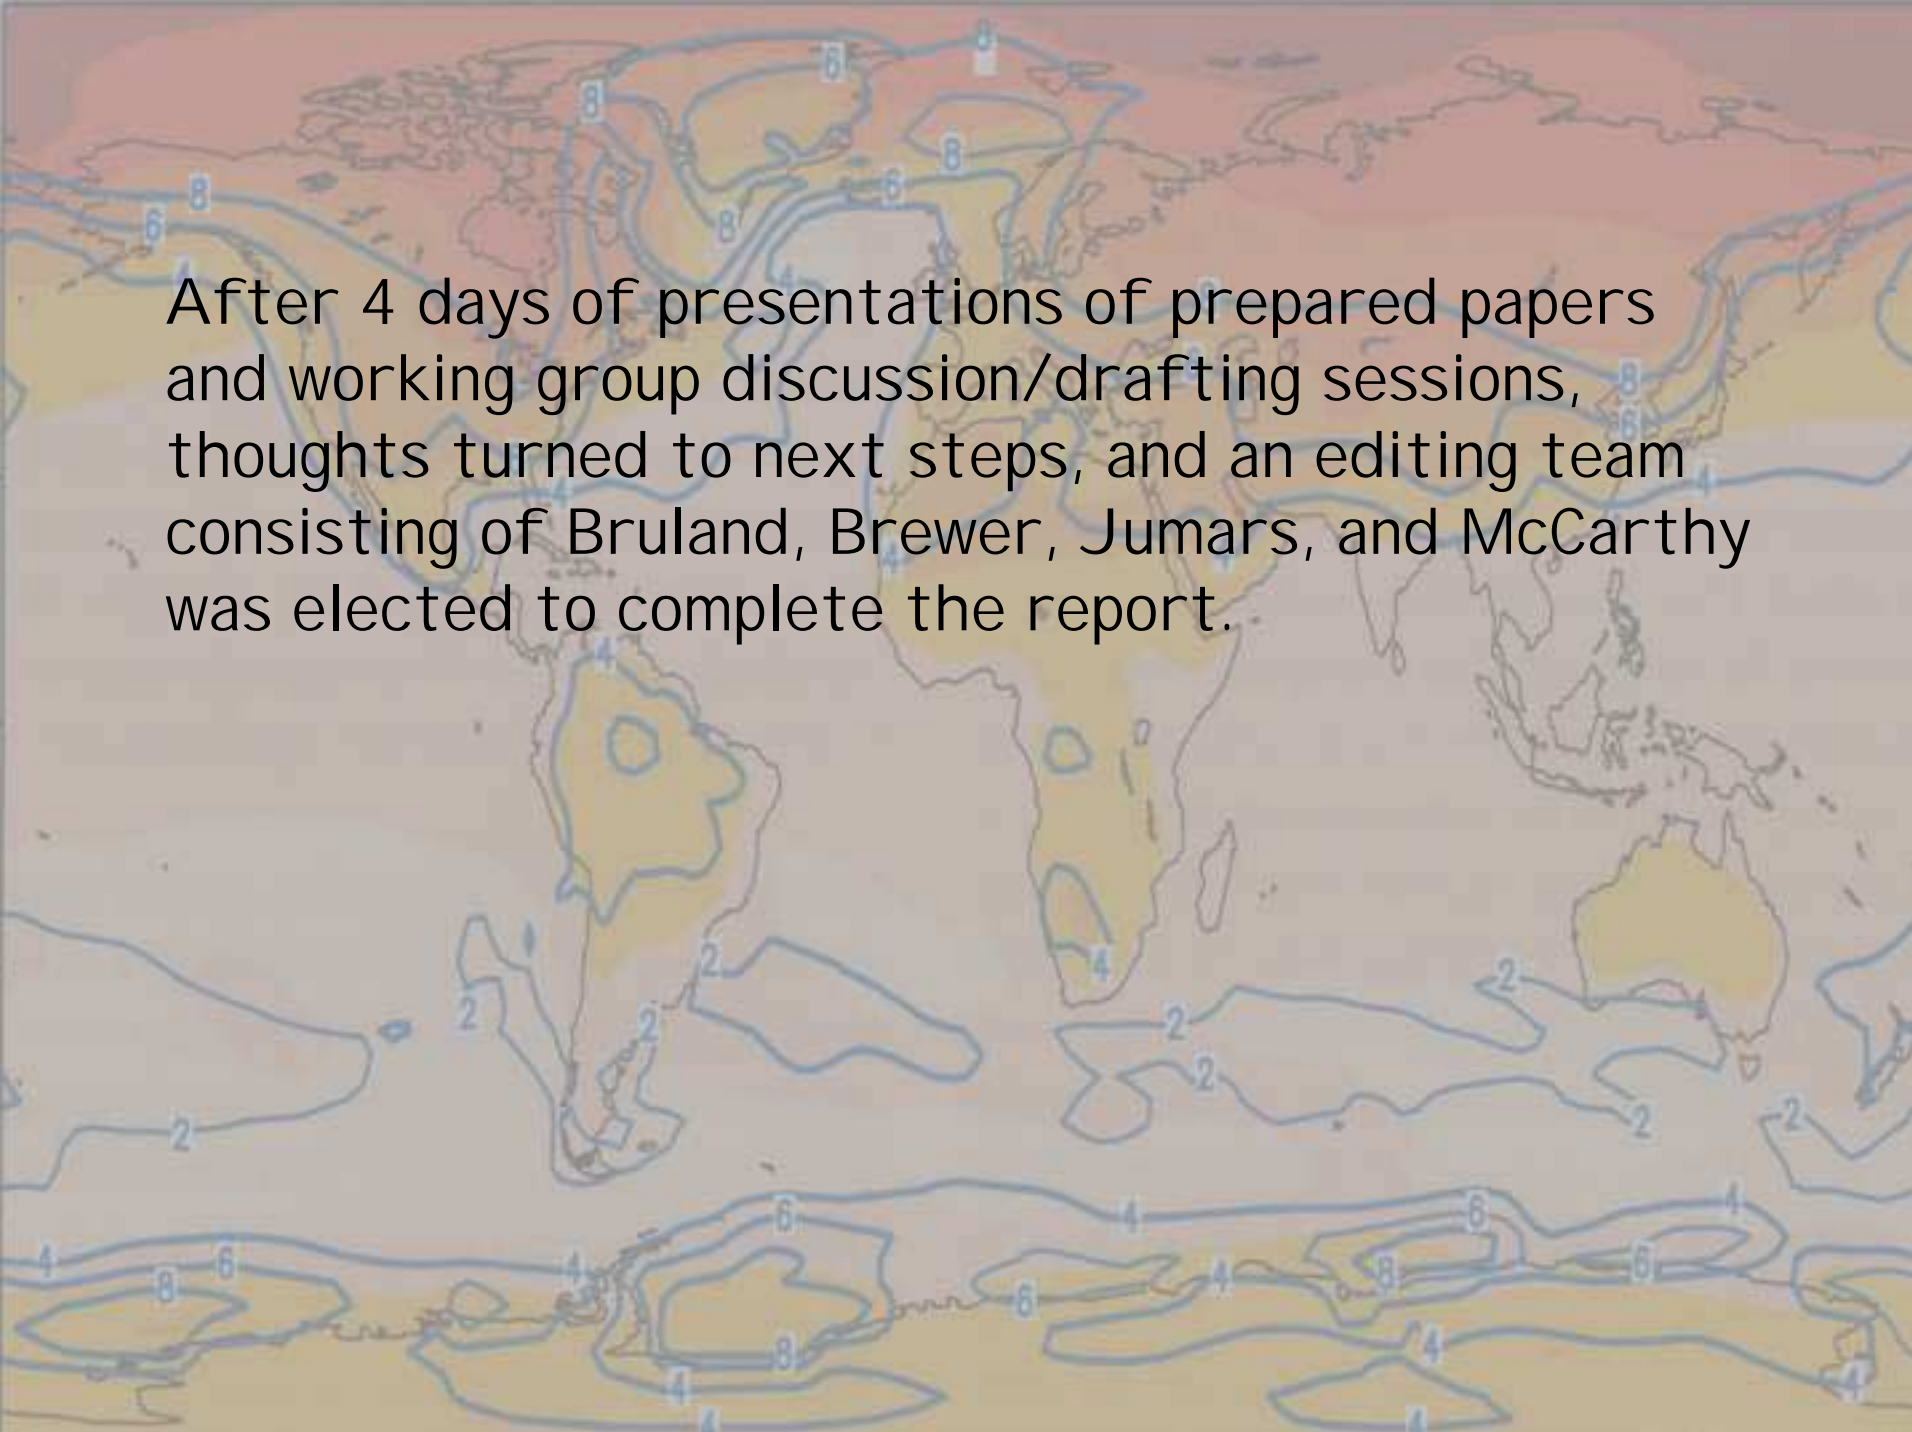

## Chapter I Statement of Goals and Objectives

---

An overall goal of a Global Ocean Flux Study (GOFS) was defined to be:

To identify and quantify the physical, chemical, and biological processes controlling biogeochemical cycling in the ocean, and their interaction with the global atmosphere. The goal is to understand the processes governing the production and fate of biogenic materials in the sea well enough to predict their influences on, and responses to, global scale perturbations.

After 4 days of presentations of prepared papers and working group discussion/drafting sessions, thoughts turned to next steps, and an editing team consisting of Bruland, Brewer, Jumars, and McCarthy was elected to complete the report.

Washington, D.C. 1984

# Lesson Learned

Academy Boards etc. can be useful.

But do they have similar relevance today?

To some degree this vetting role for science like JGOFS occurs today as part of the IGBP and WCRP programmatic function.

# Some Important Dates

- November 1982 - Ocean Science Board meeting
- March 1983 - Small Cambridge meeting
- June 1983 - Letter from Board on Ocean Science and Policy to James Beggs, Administrator of NASA
- May 1984 - Boston Planning Meeting
- September 1984 - The Woods Hole workshop
- December 1984 - The workshop report was complete

*One critical constant in all of this*

John Steele

Another giant who was working behind the scenes...

# Roger Revelle

Coined the phrase “biological pump”

November 1984 - Roger proposed to the now defunct Committee on Climate and the Ocean (CCCO) that a Program be launched to improve understanding of the Carbon Dioxide Cycle in the Ocean with 2 objectives

- 1) Measurements of the constituents of the CO<sub>2</sub> system in surface and subsurface waters...
- 2) Studies of the interaction between biological activity and atmospheric and oceanic carbon dioxide...

# Lesson Learned

Old guys and gals can be helpful, but at some point those who are going to do the science for the next 10 - 20 years have to take charge

# "Coastal Zone Color Scanner" (CZCS) May 1979

*Oceanography from Space*

**OCI**  
*Ocean Color Imager*

*Ocean color observations:  
a new environmental  
perspective*

# Ready For Implementation

Both the research and operational communities are prepared to exploit the capability offered by an OCI.

*Week-long albacore tuna catch (circles) correlated with outer edge of upwelled water on 21 September 1981, demonstrating the utility of ocean color for fishery forecasts*

## *International Programs on Climate and Global Change*

- The World Climate Research Program (WCRP) has two major oceanographic efforts — World Ocean Circulation Experiment (WOCE) and Tropical Ocean and Global Atmosphere (TOGA).
- WOCE and TOGA will study surface-wind forcing, ocean-current response, and air-sea heat exchange.
- The Global Ocean Flux Study (GOFS) will investigate global chemical and biological fluxes in the ocean, ranging from phytoplankton production at the surface to formation of the sedimentary record on the sea floor.
- Together with WOCE and TOGA, GOFS will provide the basis for an improved understanding of global biogeochemical processes.

## *Simultaneous Satellite Observations Required*

- Simultaneous satellite observations of winds, currents, surface temperature, and ocean color are required to support these international programs.
- These requirements can be met by the scatterometer aboard NROSS for winds, TOPEX for currents, and the infrared radiometer and OCI aboard a NOAA satellite for temperature and color.

## *Ocean Forecasting*

- On regional and global scales, these simultaneous observations will lead to a new understanding of the dependence of phytoplankton productivity on winds, currents, and temperature.
- Together with numerical models, the data will enable improved marine forecasting for operational applications.

*Shown are seasonally averaged phytoplankton-abundance images (off Baja California, 1979) indicating a dramatic increase in the fall. This is an example of a new observational basis to relate biological and physical processes over seasonal and longer scales.*

The background of the slide is a map of the Pacific Ocean region, showing contour lines and numerical values. The contours are labeled with numbers such as 2, 4, 6, and 8, indicating depth or a specific variable. The map covers the area from the North Pacific to the South Pacific, including the western coast of North America, the Hawaiian Islands, and the eastern coast of Australia.

# *Ready For Implementation*

Both the research and operational communities are prepared to exploit the capability offered by an OCI.

# TTO SURFACE (1-15M)

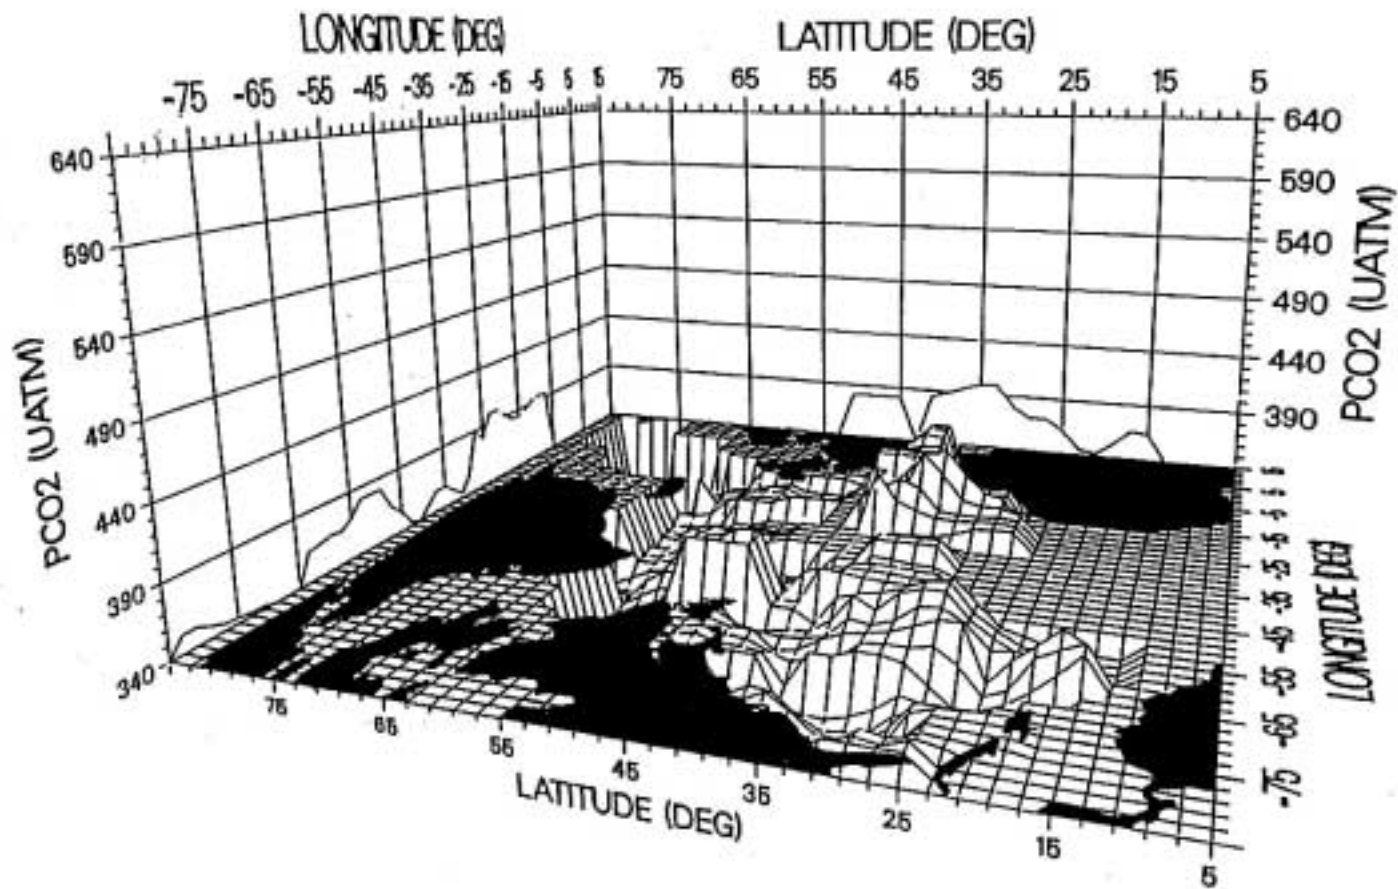

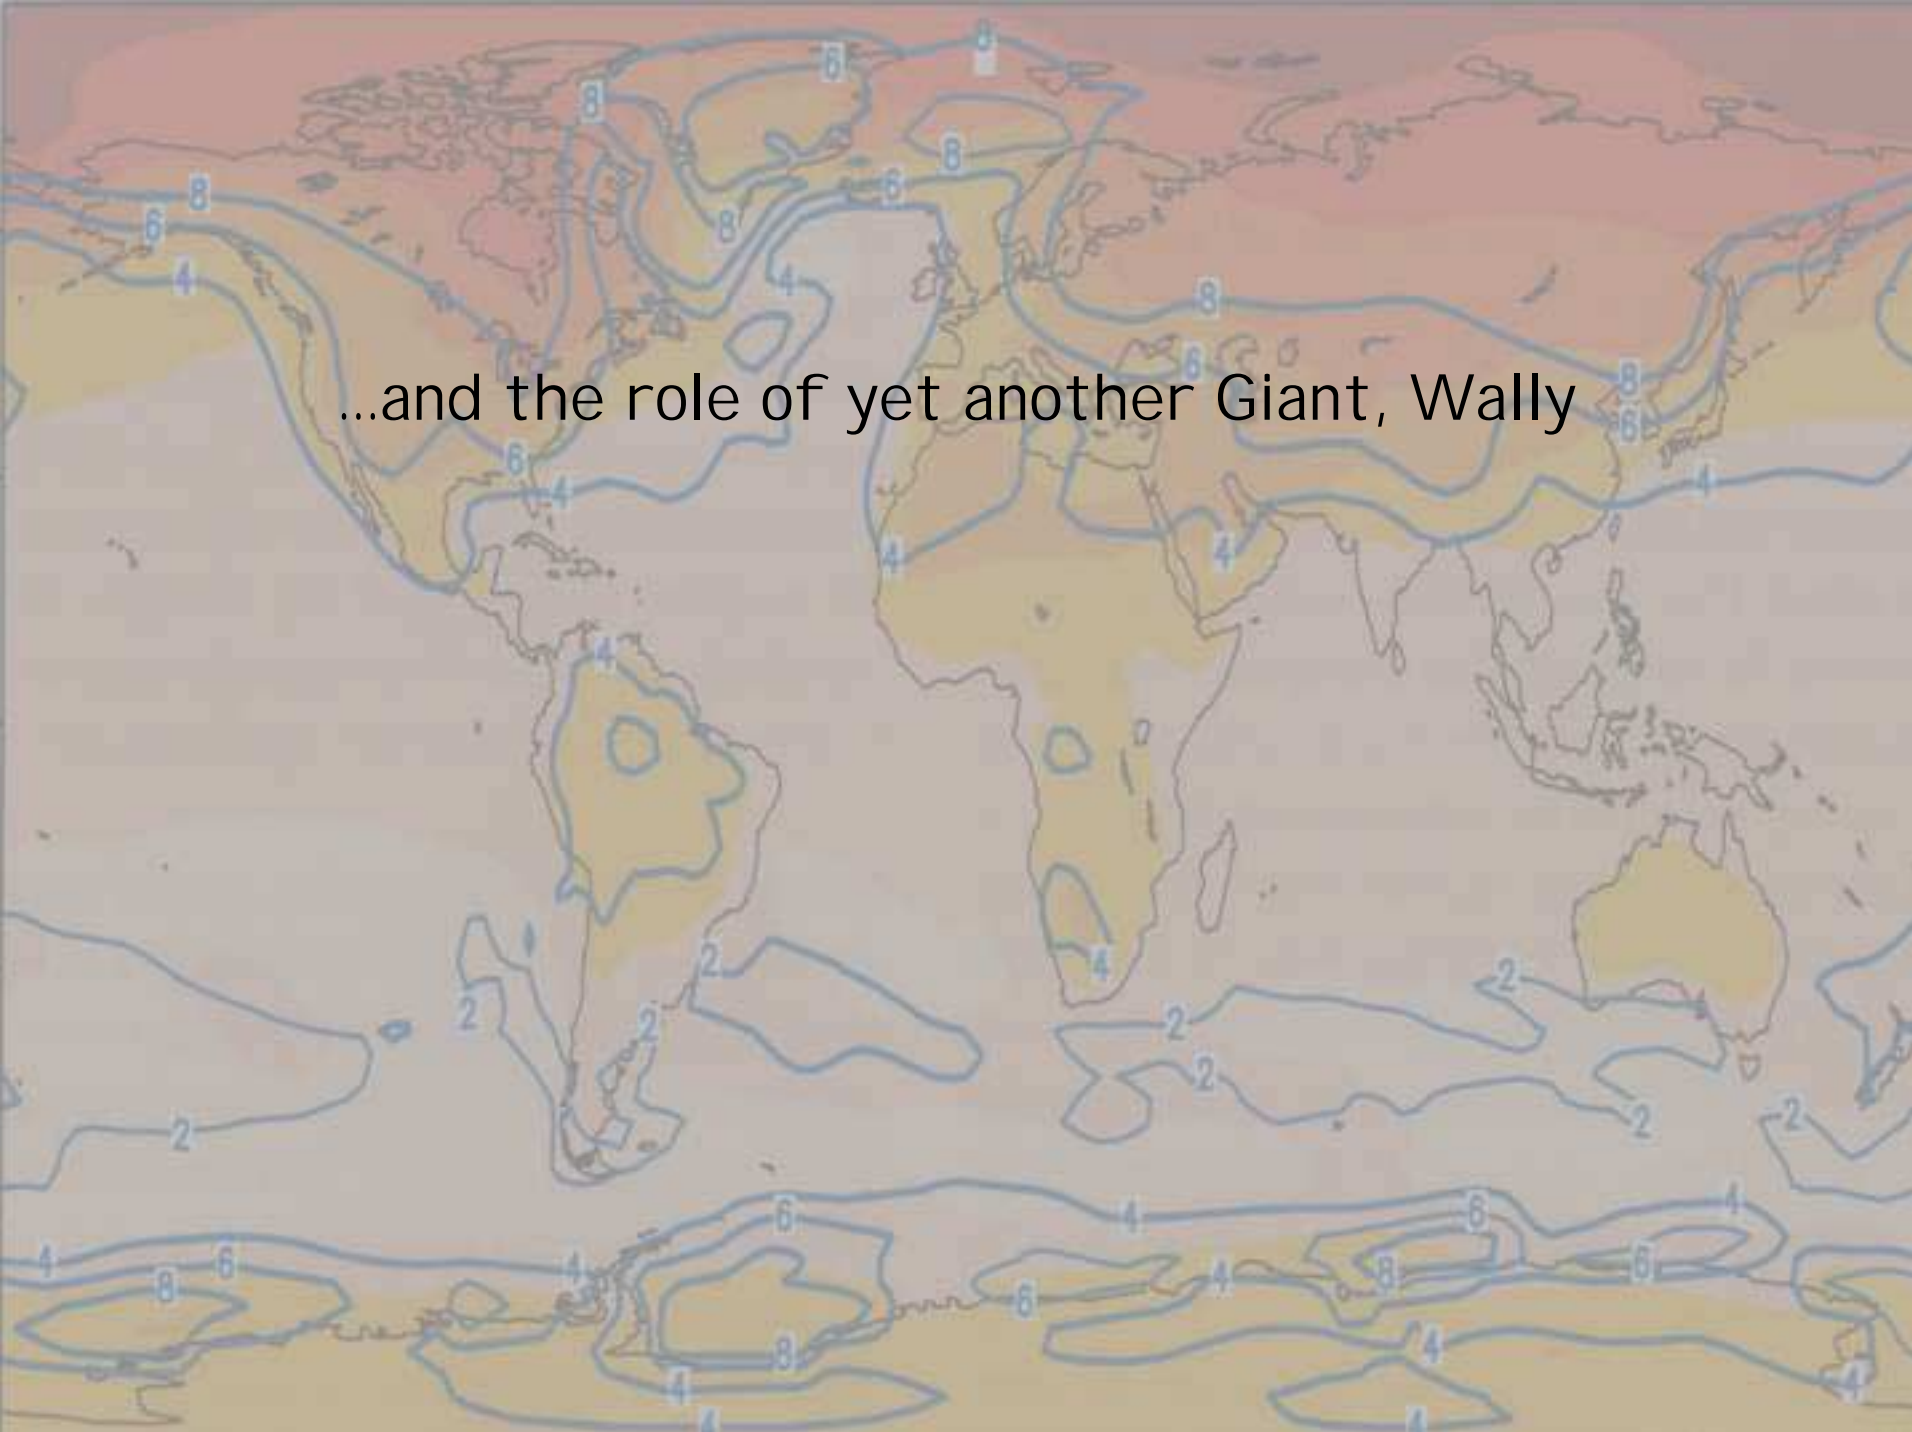

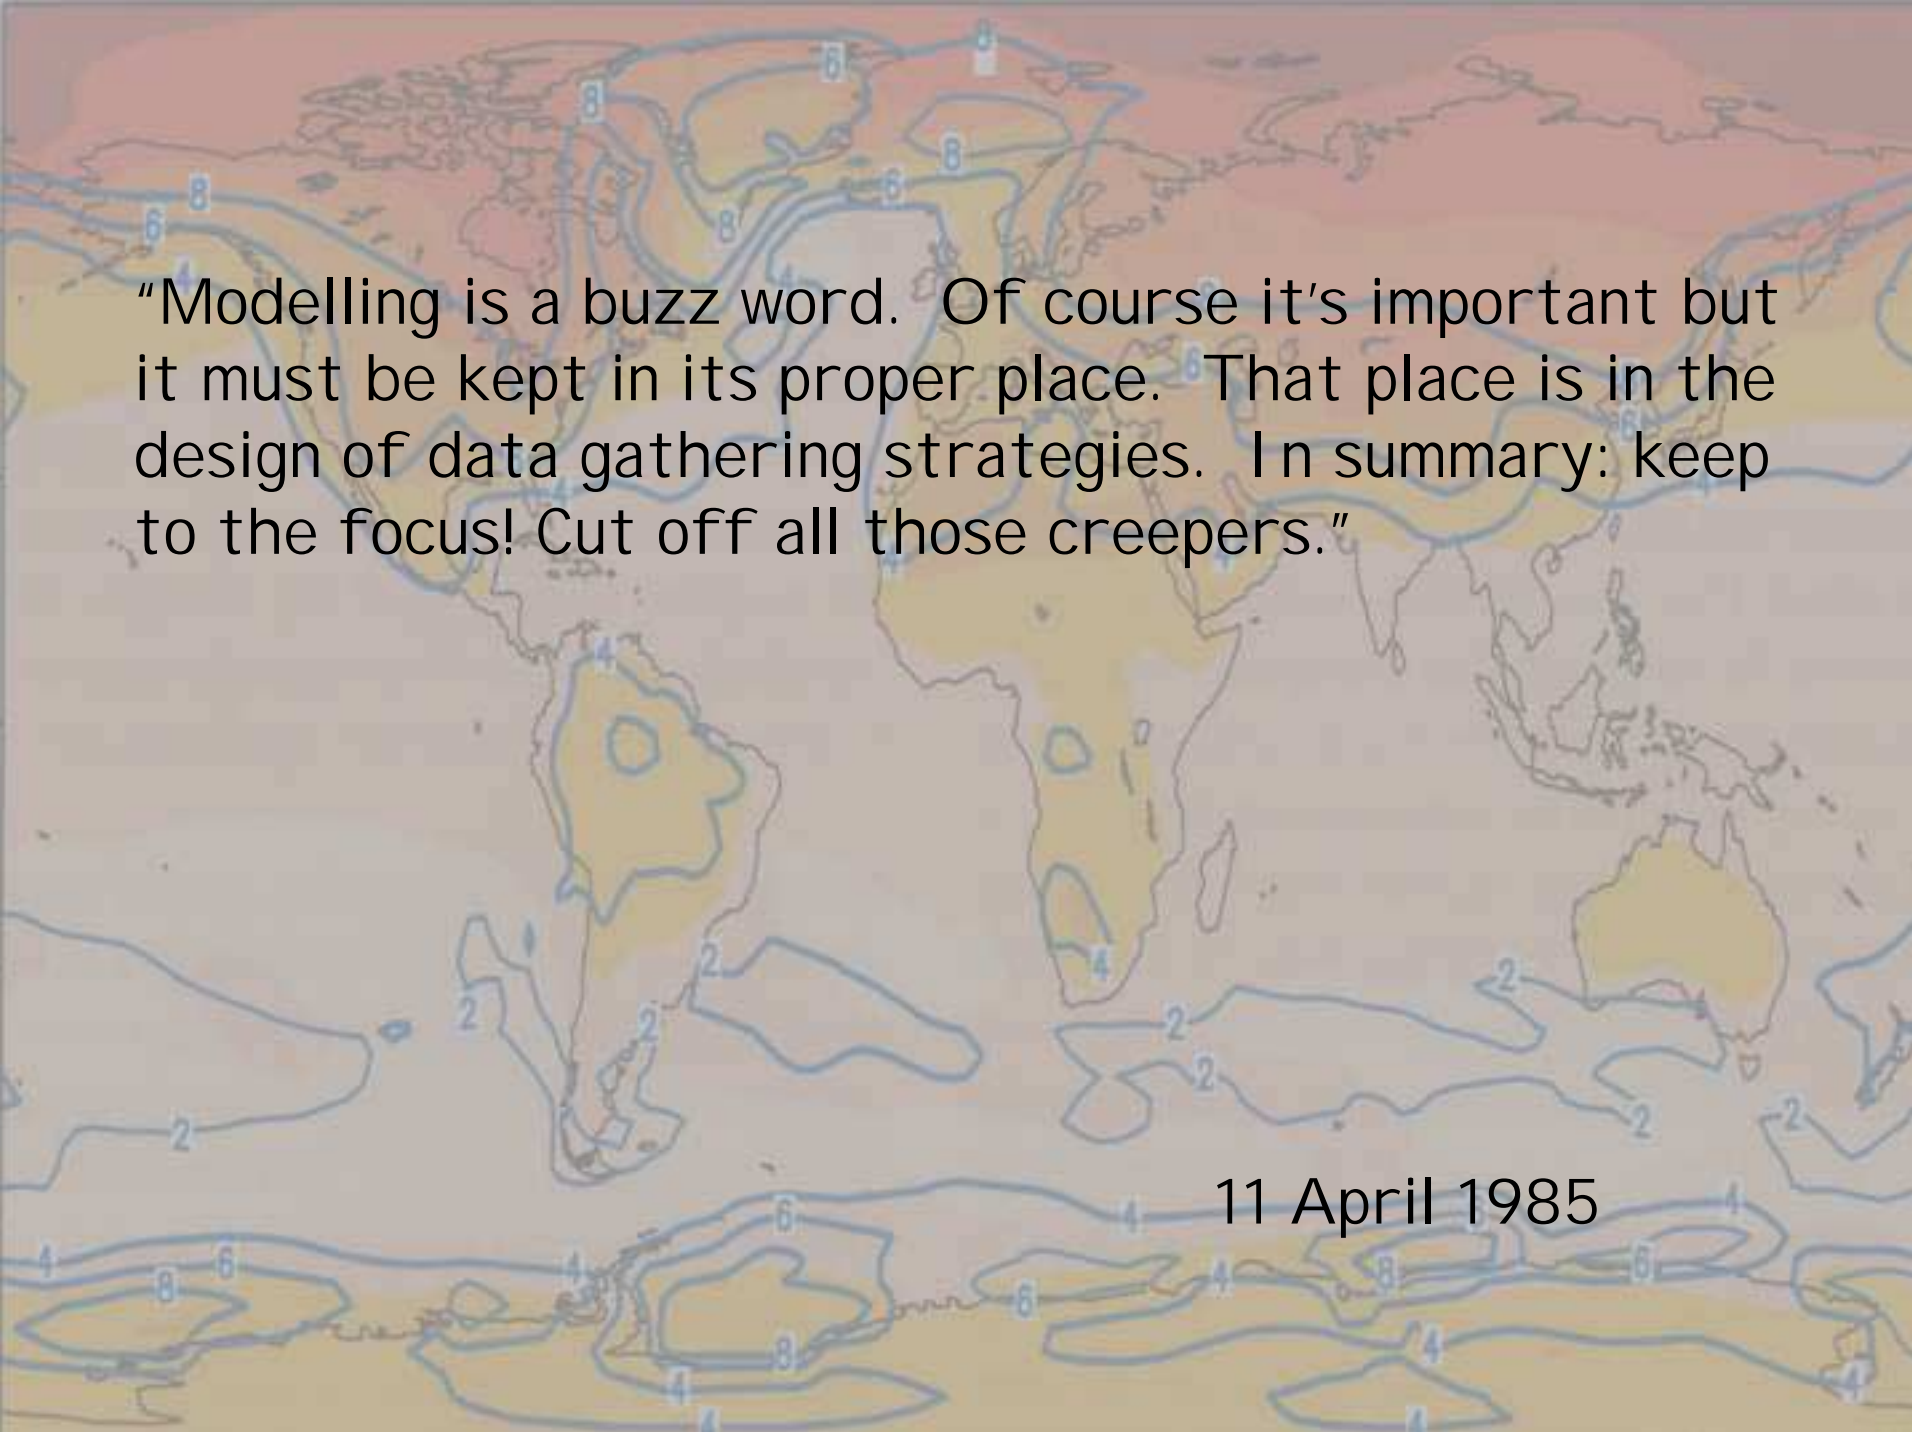

Figure 4. The partial pressure of CO<sub>2</sub> gas in surface seawater expressed as a departure from atmospheric equilibrium. Units are parts per million in volume terms, expressed as microatmospheres. Negative values, or "holes" imply a CO<sub>2</sub> flux from the atmosphere to the ocean, and "peaks" imply a CO<sub>2</sub> flux from the ocean to the atmosphere. (Courtesy Dr. Peter Brewer, WHOI)

McCarthy, Brewer, and Feldman 1986

...and the role of yet another Giant, Wally

“Modelling is a buzz word. Of course it’s important but it must be kept in its proper place. That place is in the design of data gathering strategies. In summary: keep to the focus! Cut off all those creepers.”

11 April 1985

**AN OCEAN PARTICULATE PROGRAM – BROECKER'S STRAWMAN**

Circa 1985

The background of the slide is a map of the North Atlantic Ocean. It features contour lines representing isotherms (temperature) and bathymetry (depth). Isotherms are labeled with values such as 4, 6, 8, and 10. Bathymetric contours are labeled with values like 100, 200, 300, 400, 500, 600, 700, 800, 900, 1000, 1500, 2000, 2500, 3000, 3500, 4000, 4500, 5000, and 6000. The map shows the coastline of North America and Europe, with the Gulf Stream and other oceanic features indicated by the contour lines.

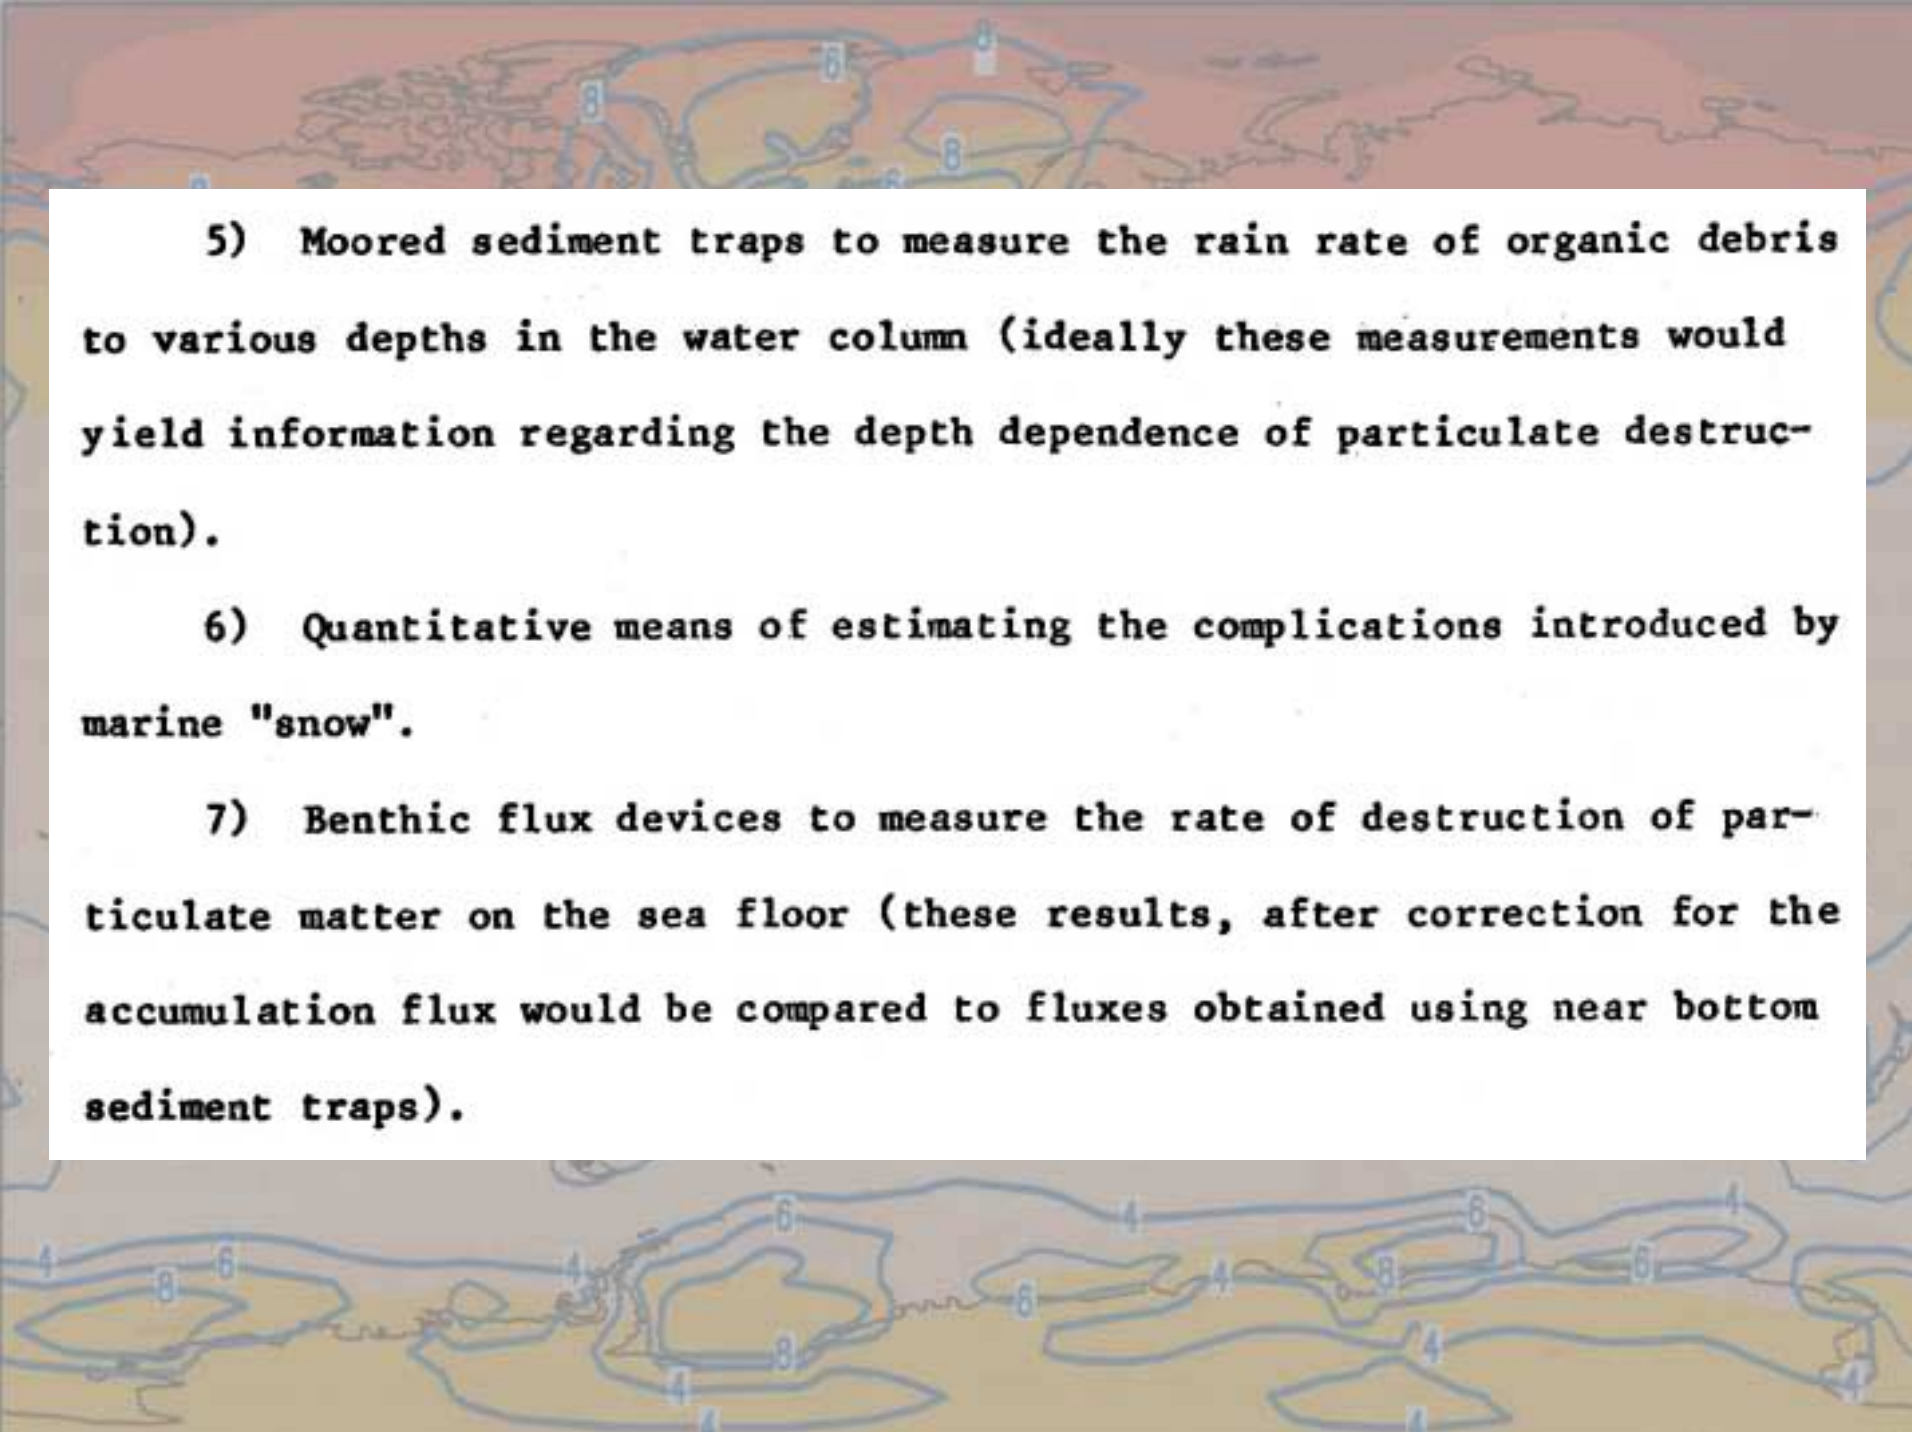

## **OBJECTIVES**

- 1) To define the rate of production of organic matter\* as a function of geographic location and season.
- 2) To define the rain rate of organic particulate matter from the photic zone into the upper thermocline as a function of geographic location and season.
- 3) To define the destruction rate (by respiration and dissolution) of particulate matter as a function of geographic location and depth in the sea.

## TECHNIQUES

- 1) Color scanning satellite to determine spacial pattern of ocean chlorophyll concentration.
- 2)  $^{14}\text{C}$ ,  $^{18}\text{O}$ ,  $\text{O}_2$ ,  $\Sigma\text{CO}_2$  measurements for sea truth of the relationship between color as measured by satellite and rate of water column photosynthesis.
- 3) Measurements of the ratio of calcite and of opal production to the rate of photosynthesis as a function of geographic location and season.
- 4) Floating sediment traps (and perhaps in situ filtration) to measure the rain rate of organic particulates from the photic zone (i.e., to establish the relationship between the rate of water column photosynthesis and the rain rate of organic particulates).

The background of the page is a map with contour lines and numerical values. The contours are drawn in a light blue color and represent various levels or depths. The numbers, also in light blue, are scattered across the map, with some appearing in the center and others towards the edges. The map itself is a light tan or beige color, suggesting a topographic or bathymetric chart.

5) Moored sediment traps to measure the rain rate of organic debris to various depths in the water column (ideally these measurements would yield information regarding the depth dependence of particulate destruction).

6) Quantitative means of estimating the complications introduced by marine "snow".

7) Benthic flux devices to measure the rate of destruction of particulate matter on the sea floor (these results, after correction for the accumulation flux would be compared to fluxes obtained using near bottom sediment traps).

## **SCIENTIFIC APPLICATION**

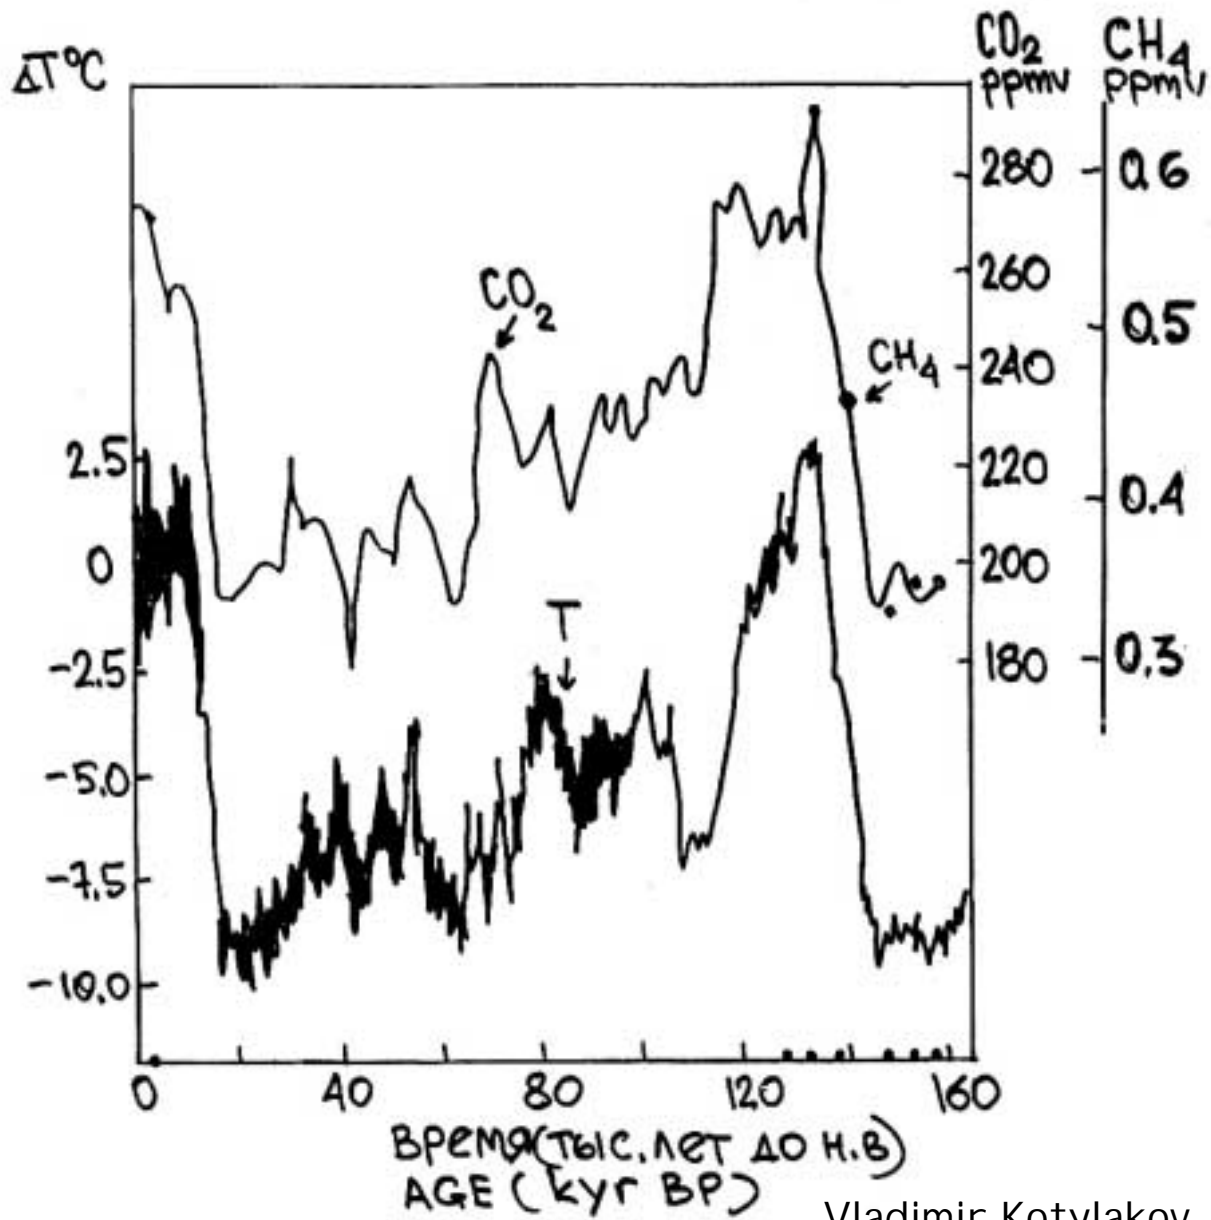

- 1) A knowledge of the rates of photosynthesis and respiration as a function of space and time in the sea is fundamental to any understanding of the "ecology" of marine organisms.
- 2) A knowledge of the production and dissolution patterns of opal and calcite hard parts is fundamental to those wishing to read the record of paleo environments preserved in marine sediments.
- 3) A knowledge of the pattern of nutrient transport to the ocean's surface and of the pattern of nutrient regeneration in the sea's interior will provide powerful constraints on models of water flow through the sea.

The background of the slide is a map with contour lines. The lines are labeled with the numbers 2, 4, 6, and 8. The map shows a large area with these contours, possibly representing a geographical or atmospheric variable. The colors are muted, with a light tan background and blue contour lines.

## **FATAL FLAWS?**

Beyond the many questions about the basic reliability of any of the above techniques there is a question of geographic coverage. To the extent that the production and rain of particulates is concentrated along the margins of the sea, the sampling problem becomes a very difficult one.
